

Qpack2 – atmospheric retrievals by OEM in Matlab

Patrick Eriksson
(patrick.eriksson@chalmers.se)

May 17, 2010

1 Scope

Qpack2 is a retrieval system, implemented in Matlab, for performing inversions of atmospheric observations inside the framework of “optimal estimation” (OEM). So far, only cases where the aim is to retrieve vertical profiles of atmospheric quantities (1D cases) are handled. Accordingly, the present main application areas of Qpack2 are ground-based observations and inversion of individual satellite spectra/scans. Inversion of satellite scanning sequences where atmospheric fields to be retrieved have also a latitude or longitude extension (2D or 3D) could be considered as part of future development.

The package should be general and flexible for covered measurements. For example, there is basically no limitations regarding observation geometry. Further, Qpack2 has been developed to be suitable for operational inversions, as long as not most extreme calculation speed is required. Some important aspects here are that batch calculations are allowed and atmospheric a priori profiles can automatically be extracted from climatology data.

2 Background and introduction

Qpack2 is part of the more general Atmlab package of Matlab functions. In fact, it is largely a merge of some of the systems in Atmlab. The computational engine, i.e. the forward model, of Qpack2 is ARTS-2 (not part of Atmlab). The communication with ARTS-2 is made through the Qarts system. OEM inversions are performed by the function `oem.m`. Climatology data are stored and interpolated through the `atmdata` format.

This can be seen as a direct successor of Qpack (*Eriksson et al.*, 2005), despite all code is written from scratch. However, for both Qpack versions the computations are controlled by a set of settings fields packed into a structure denoted as `Q` (though Qpack2 has also a structure `O`). Qpack was built around ARTS-1, this new Qpack version is mainly a consequence of that ARTS-2 is the maintained version of ARTS. This gave also an opportunity to make a more stringent implementation and to add some features. This should hopefully make it easier to maintain and extend Qpack2. Data formats are now more clearly defined and the ambition level around documentation is higher (but still modest). A main improvement compared to Qpack2 is that extraction of a priori data from climatology data is now an integrated part. On the other hand, the feature of classifying errors into different categories (0-3 in Qpack) and the associated plotting features are removed as it was hardly used.

ARTS-2 is below just denoted as ARTS.

Quality checks are not handled by Qpack2. For example, there is no default check that the frequencies of the measurements are as expected. This for efficiency reasons and the

fact that such checks are hard to make in a totally general manner. Checks are left for accompanying dedicated functions, such as `qp2_check_f`.

3 Software and installation

The needed software packages are ARTS and Atmlab. The simplest is to obtain and update these packages through svn. Download instructions for ARTS are found at www.sat.ltu.se/arts/getarts. The installation details are here not repeated. A plain installation of ARTS suffices.

Download options for Atmlab are found at www.sat.ltu.se/arts/tools. The file `CONFIGURE` (found in the top folder) gives instructions for how to get started with Atmlab. Qarts2 demands that several “atmlab settings” are activated. This is handled by the function `atmlab`. A description of all atmlab settings is obtained by:

```
>> help atmlab
```

At least the following atmlab settings are used: `ARTS_PATH`, `ARTS_INCLUDES`, `EXTRAP`, `FMODEL_VERBOSITY`, `VERBOSITY` and `WORK_AREA`. Some example settings:

```
atmlab( 'ARTS_PATH',          fullfile(homedir,'ARTS/arts/src/arts') );
atmlab( 'ARTS_INCLUDES',     fullfile(homedir,'ARTS/arts/includes') );
atmlab( 'EXTRAP',            true                                     );
atmlab( 'FMODEL_VERBOSITY',   0                                     );
atmlab( 'VERBOSITY',          1                                     );
atmlab( 'WORK_AREA',          '/tmp'                                );
```

The standard choice is to place these calls of `atmlab` in `atmlab_conf.m`, as described in `CONFIGURE`.

4 Documentation

The overall documentation is found in this document. The detailed information is mainly stored in the implementation files. Information on individual functions is obtained by the standard Matlab help command. For example:

```
>> help oem
```

Some of the used data structures are documented matching the requirements of `qinfo.m`. For example, to list all fields and the documentation text of Qarts' Q:

```
>> qinfo(@qarts)
```

The documentation for a specific field is obtained as

```
>> qinfo(@qarts,'F_BACKEND')
```

Wildcards are allowed when defining fields:

```
>> qinfo(@qarts,'ABS_*')
```

Details around development and bug fixes are described in the `ChangeLog` file of Qpack2 (`atmlab/retrieval/qpack2/ChangeLog`). The versions of Qpack2 are numbered as Qpack2.x.y, where x is increased when a change can not be accommodated with backward compatibility and y is increased for each change/commit.

5 Overview

A retrieval by `Qpack2` has three main steps:

```
% 1: Define forward model and retrieval settings
[Q,O] = my_q_fun;

% 2: Import the measurement data to be inverted
Y = my_y_fun;

% 3: Perform the inversion
L2 = qpack2( Q, O, Y );
```

The variables `Q`, `O`, `Y` and `L2` are all structures, and the fields of these structures are described in Section 6.

The main part of the settings defined in step 1 are found in `Q`, that match directly the `Q` of the `Qarts` interface to `ARTS`. All forward model variables are part of `Q`, and retrieval variables such as grids and a priori data are also defined in `Q`. The exceptions are settings directly associated with OEM, that are stored in `O`. This division reflects the fact that the OEM operations are made by a stand-alone function. This function, `oem`, is implemented in a general manner, to be applicable for any retrieval case as long as an interface to a “forward model” is provided.

The measurement data structure `Y` can be an array. That is, a series of observations can be inverted in a single call of `qpack2`, on the condition that a `Q` and `O` are valid for all observations. This implies e.g. that basic sensor characteristics such as backend frequencies must be common for all the data cases in `Y`. On the other hand, both observation position and direction can differ between the observations, and the data from e.g. an aircraft flight could be inverted in a single run.

The usage of the (dummy) functions `my_q_fun` and `my_y_fun` in steps 1 and 2 is just a suggestion for how to organise the definition phase of the run, but it is probably a good idea to separate the inversion settings and the task of importing measurement data.

When `Q`, `O` and `Y` are created, it is just to call `qpack2`, and everything should work automatically. The input of `qpack2` is fixed (throughout `Q`, `O` and `Y`). The output is normally the result of the retrieval, packed as a “level 2” data structure (`L2`). The function can also provide simulated measurements. This option is triggered by setting the spectrum field to be empty (if `Y` is an array, this must be done for elements):

```
...
Yempty.Y = [];
Ysim = qpack2( Q, O, Ye );
```

The output is a copy of `Ye`, with the field `Ysim.Y` set to the result of the forward model run. The simulated data match the a priori state of the retrieval set-up.

A full example is found in the file `qpack2_demo` (placed in the folder `demos`). The example works with simulated data, created by `qpack2` itself. The example file is also appended to this document as Appendix A. A related example is `arts_oem_demo`. It does not use `Qpack2`, but shows how an OEM inversion is performed with `ARTS` as the forward model, and the calculation steps in this example gives a good view of the inside of `Qpack2`.

6 Main data structures

6.1 Forward model and retrieval settings

6.1.1 General features

Forward model parameters and most retrieval variables are joined into a single structure, denoted as **Q**. This structure has a fixed set of fields. That is, the structure must always contain exactly this set of fields. However, some fields are used only in particularly circumstances and not all fields must be set. A field of **Q** is flagged as undefined by setting it to `{}`, and e.g. `[]` is taken as an active selection. This applies also to structures **O** and **Y**.

The structure **Q** of Qpack2 is identical to the **Q** of Qarts. Qpack2 makes only slight modifications of **Q** before it is given to Qarts. The Qarts system is primarily an interface to the ARTS forward model, on the same time as retrieval variables can be defined in a relatively general manner. However, Qarts is not a complete retrieval system, it just allows definition of retrieval variables in parallel with the forward model data. The ambition is just to provide the basis for retrieval systems, such as Qpack2 or streamlined software dedicated to a single sensor.

Qarts is documented through the `qinfo` feature:

```
>> qinfo(@qarts)
```

The call of `qinfo` above provides a description of all defined fields (Sec. 3) and this information is also found here as Appendix B. It is recommended to initialise **Q** as

```
Q = qpack2;
```

This ensures that **Q** contains all defined fields, also ones introduced more lately. If any field is added to **Q**, it shall not change the result of older setting files. If a needed addition can not be accomodated with backward compability, this generates a new version of Qarts.

All features of ARTS can be accessed through Qarts. Calculations of standard type can largely be handled by defining the fields of Qarts that have a direct matching ARTS workspace variables (WSV). That is, the name is the same in Qarts and ARTS, beside that Qarts use uppercase for its fields and ARTS lowercase for its variables (e.g. `Z_SURFACE` and `z_surface`, respectively). Qarts has also several fields that allow inclusion of workspace method (WSM) calls. Some of these fields match ARTS agendas and have then a dedicated purpose (e.g. `SURFACE_PROP_AGENDA`). There are also fields where you are free to include any set of WSM calls (e.g. `WSMS_BEFORE_RTE`). You can also use ARTS's include feature through the field `INCLUDES`.

Accordingly, Qarts is a relatively clean and open interface to ARTS, and to set-up a calculation demands primarily an understanding of ARTS. Built-in documentation of ARTS WSMs and WSVs is obtained in a terminal as

```
$ arts -d z_surface
```

or from within Matlab as

```
>> arts('-d z_surface');
```

See the documentation of ARTS for more in-depth documentation.

The best introduction to the practical usage of ARTS is obtained through the control file examples found in ARTS's folder `tests`. For an introduction of the usage of ARTS through Qarts, there are several example scripts in Atmlab's folder `demos`, such as `qarts_demo`.

6.1.2 Qpack2 specifics

Most fields of `Q` can be unspecified (`{}`), but Qpack2 handles some fields in special way:

- `Q.ATMOSPHERE_DIM` must be set, to 1.
- `Q.R_GEOID` must be set.
- `Q.Q.USE_RAW_ATMOSPHERE` must be set to false.
- `Q.ABS_SPECIES.ATMDATA` must be set.
- `T_ATMDATA` must be set. Geometrical altitudes of the pressure levels (the `WSV z_field`) are found by applying hydrostatic equilibrium.
- `Q.ABSORPTION` must be set. If this field is set to 'CalcTable' and `Q.ABS_P` is unspecified, the function `qarts_abstable` is called (with default arguments) for each retrieval case (using the a priori state as the reference for the absorption table calculations). If you want to use a single absorption table, this table must be generated separately.
- `Q.TNOISE_C` must be set.
- The a priori knowledge covariance matrix (`Sx`) is created by `arts_sx` and the `SX` sub-fields of the retrieval quantities must be set.

6.2 OEM settings

Settings directly associated with OEM are put into the structure `O`. Also this setting structure is documented through `qinfo` (see also Appendix C):

```
>> qinfo(@oem)
```

Many of the fields of `O` controls the output of the `oem` function. For Qpack2 you do not need to set these fields manually. The output required to provide the specified L2 data (Section 6.4) is ensured by initialising `O` as

```
O = qp2_l2( Q );
```

For linear inversion, a single active setting is needed:

```
O.linear = true;
```

6.3 Measurement data

The series of measurements (spectra or scans) to be treated is packed into a data structure denoted as `Y`. The data fields of this structure are described in `qp2_y`, following the `qinfo` format:

```
>> qinfo(@qp2_y)
```

The same information is appended to this document in Appendix D. An example:

```
>> Y(3)
```

```
ans =
```

```
      DAY: 3
      F: [800x1 double]
      HOUR: 11
      HSE_P: 10000
      HSE_Z: 1.5677e+04
      LATITUDE: 57.4000
      LONGITUDE: 11.9300
      MINUTE: 57
      MONTH: 3
      SECOND: 58.0000
      TNOISE: 0.0243
      Y: [800x1 double]
      YEAR: 2002
      ZA: 65
      Z_PLATFORM: 5
```

The simplest way to initialise Y is to use `qp2_y` as

```
for i = 1 : n
    Y(i) = qp2_y;
    load( file{i} )
    Y(i).Y = ...
end
```

6.4 Retrieved data

Retrieved data are returned as a structure array `L2`, with one element for each element in `Y`. The fields of `L2` are not fixed, the set of returned fields depend on settings in `Q`. This makes it impossible to use `qinfo` here (as for `Q` and `Y`), and the fields are instead described below in this document.

The only mandatory field of `L2` is `converged`. The remaining content of `L2` is controlled by the Qarts field `L2_EXTRA` and the `L2` sub-field for the retrieval quantities (e.g. `Q.POLYFIT.L2`). As an example on a complete `L2`, the first element of the output of `qpack2_demo` is (the polyfit part is truncated):

```
>> L2(1)
```

```
ans =
```

```
      year: 2008
      month: 2
      day: 25
      hour: {}
      minute: {}
      second: {}
      converged: 1
      dx: 4.4374e-06
```

```

        cost: 1.0748
        cost_x: 5.8390e-04
        cost_y: 1.0742
        f: [1279x1 double]
        y: [1279x1 double]
        yf: [1279x1 double]
        bl: [1279x1 double]
        p_gridid: '/tmp/Tmp28011/p_grid.xml'
        t_field: '/tmp/Tmp28011/t_field.xml'
        z_field: '/tmp/Tmp28011/z_field.xml'
species1_name: '03'
        species1_p: [45x1 double]
        species1_xa: [45x1 double]
        species1_x: [45x1 double]
        species1_e: [45x1 double]
        species1_eo: [45x1 double]
        species1_es: [45x1 double]
        species1_mr: [45x1 double]
        ffit_xa: 0
        ffit_x: -3.8104e+03
        ffit_e: 8.7798e+03
        ffit_eo: 8.6418e+03
        ffit_es: 1.5504e+03
        ffit_mr: 0.9692
polyfit0_xa: 0
        polyfit0_x: 0.0516
        polyfit0_e: 0.4748
        polyfit0_eo: 0.0967
        polyfit0_es: 0.4649
        polyfit0_mr: 0.7745
polyfit1_xa: 0
        polyfit1_x: -0.0022
        polyfit1_e: 0.0097
        polyfit1_eo: 0.0094
        polyfit1_es: 0.0023
        polyfit1_mr: 0.9996

```

A description of the options for Q.L2_EXTRA is obtained by:

```
>> help qp2_l2
```

Further comments and description of fields directly associated with specific retrieval quantities are found below (no ambition of completeness here).

6.4.1 Varous general fields

cost, cost_x and cost_y:

Cost values of retrieved state and fit to measurement. See further `oem.m`.

P.year, P.month, P.day, P.hour, P.minute, and P.second:

The time of the measurement.

P.latitude and **P.longitude**:

The geographical position of the measurement.

tnoise:

Mean of assumed thermal noise. This is simple average, no weighting with channel widths is applied. This value has no direct physical meaning, but can be used as a mean to e.g. remove the most noisy measurements (without having **Y** at hand).

f:

Frequency vector of measurement. Equals **Y.F** if set, otherwise **Q.F_BACKEND**.

y:

Measured spectrum.

yf:

Fitted spectrum. That is, the spectrum matching retrieved state vector.

baseline:

Retrieved “baseline”. That is, retrieved spectrum distortion through e.g. polynomial fitting. A scalar 0 if no baseline retrieval is performed.

converged:

Convergence flag. See further **oem.m**.

dx:

Change in the state vector **x** between each iteration. See further **oem.m**.

6.4.2 Background atmospheric state

p, **t** and **z**:

A consistent set of pressure, temperature and altitude vectors. The vectors are identical to the ones that are provided to the forward model. If temperatures are retrieved, this information is used. Otherwise returned data match climatology temperatures.

6.4.3 Retrieved species

The retrieved species are indexed after the order they are specified in **Q** and named as **species1**, **species2** ... A number of fields is returned for each species. The field names below are valid for species 1. If two species are retrieved there is also a field named as **species2_name** etc. This set of fields are available:

species1_name:

Tag name of species.

species1_p:

Vertical/pressure retrieval grid for the species.

species1_x:

Retrieved profile. Unit depends on **Q.SPECIES(i).UNIT**.

species1_xa:

A priori state for the species.

species1_e:

Total retrieval (observation + smoothing) error for the species.

species1_eo:

Observation error for the species.

species1_es:

Smoothing error for the species.

species1_mr:

Measurement response for the species. This is the sum of the rows of **species_A** (see below).

species1_A:

The species specific averaging kernels. That is, this is the diagonal centred sub-matrix covering only the resolution between changes of the species at different altitudes. The resolution between variables of different retrieval quantities is thus not covered.

6.4.4 Baseline fit variables

There is so far only a single main approach for baseline fits, POLYFIT. A set of fields is added for each polynomial coefficient, and for the first polynomial coefficient they are

P.polyfit0_x, P.polyfit0_xa, P.polyfit0_e, P.polyfit0_eo, P.polyfit0_es and P.polyfit0_mr:

As corresponding fields above for species (**species1_x** etc.).

6.4.5 Frequency fit variables

If only a “frequency shift” retrieval is performed, the fields listed below hold scalars. If also a “stretch fit” is made, the fields are vectors of length 2. The set of fields are:

P.ffit_x, P.ffit_xa, P.ffit_e, P.ffit_eo, P.ffit_es and P.ffit_mr:

As corresponding fields above for species (**species1_x** etc.).

7 Data types and file formats

7.1 Qpack2 variables

The data types in Qpack2 (and in Qarts) follow largely ARTS. Regarding basic data types, there are two main things to consider. Firstly, a distinction is made between the logical 0 and 1, and the integers 0 and 1. Accordingly, booleans, sometime also denoted as flags, must be set to **true** or **false**. Secondly, vectors are demanded to be columns.

A notable feature of Qpack2 and Qarts is that data fields, booleans and scalars excluded, can either be set directly or be set to the name of a file (including data of the expected type). Both these settings are possible

```
Q.F_GRID = [ 501.18e9 : 1e6 : 501.58e9 ]';  
Q.F_GRID = 'f_odinsmr_ac2a.xml';
```

Note the transpose in the first case (to create a column vector).

The fields **Q.ABS_SPECIES.ATMDATA**, **Q.T_ATMDATA** and **Q.Z_ATMDATA** are intended for data of climatology character. The data format used here is called **atmdata**. The format is similar to the **GriddedField** format in ARTS, but has also fields for e.g. units. The **atmdata** format is based on the general **gformat**:

```
>> help gformat
```

For a description of the specialities of **atmdata**:

```
>> help isatmdata
```

For example, the MSIS temperature climatology found in arts-xml-data is stored as GriddedField4 but imported as

```
Q.T_ATMDATA = gf_artsxml( fullfile( arts_xmldata_path, 'climatology', ...  
                                   'msis90', 'msis90.t.xml' ), 'Temperature', 't_field' );
```

data of atmdata type are obtained:

```
>> Q.T_ATMDATA
```

```
ans =
```

```
      TYPE: 'atmdata'  
      NAME: 'Temperature'  
    SOURCE: [1x65 char]  
       DIM: 4  
     DATA: [4-D double]  
  DATA_NAME: 'Temperature'  
  DATA_UNIT: 'K'  
    GRID1: [141x1 double]  
  GRID1_NAME: 'Pressure'  
  GRID1_UNIT: 'Pa'  
    GRID2: [19x1 double]  
  GRID2_NAME: 'Latitude'  
  GRID2_UNIT: 'deg'  
    GRID3: 0  
  GRID3_NAME: 'Longitude'  
  GRID3_UNIT: 'deg'  
    GRID4: [13x1 double]  
  GRID4_NAME: 'doy'  
  GRID4_UNIT: ''
```

7.2 File formats

The standard format for data input files is “ARTS xml”. These files are hardly created by hand, but stored from Matlab (through `xmlStore`) or from ARTS (through `WriteXML`). If ARTS is compiled with support for NetCDF, that format can also be used (`arts_nc_write_datatype` and `WriteNetCDF`, respectively).

% Add a constant "baseline shift" for measurement 2
%
Y(2).Y = Y(2).Y + 1;

```

B The fields of Q

ABSORPTION:

String describing how absorption shall be calculated/obtained.

Existing options are:

`{}` : Absorption variables defined by include files. All absorption fields below will be ignored.

`'OnTheFly'` : Absorption is calculated for each propagation path point. The agenda `*abs_scalar_gas_agenda*` must here be set by an include file. No other absorption variables need to be set.

`'CalcTable'`: Calculate and use an absorption look-up table. See `*qarts_set_abs_lookup*` for simple setting of needed variables.

`'LoadTable'`: Load and use pre-calculated absorption look-up table, defined by field `*ABS_LOOKUP*`.

ABS_LINES:

The data on spectroscopic lines to use. Can be given in two ways:

1. As a file name. All formats handled by arts can then be used. See `ABS_LINES_FORMAT`. The reading is not restricted to any frequency range.
2. As an array of line data. This option is only allowed when `ABS_LINES_FORMAT` is set to `'Arts'`.

ABS_LINES_FORMAT:

The format of spectroscopic data.

Possible line formats are `'Arts'`, `'Hitran'`, `'Jpl'` and `'Mytran2'`. Note that these strings must be given exactly as stated here (first upper case etc.).

The field can further be set to `'None'` which indicates that no line data shall be included (the WSV `*abs_lines_per_species*` is set to be empty).

ABS_LINESHAPE:

The line shape to use. The same line shape is used for all tag groups. Shall be a string. Do `"arts -d abs_lineshapeDefine"` to list valid options.

ABS_LINESHAPE_CUTOFF:

The line shape cut-off to apply. The same cut-off is used for all tag groups. A value of `-1` means no cut-off. Do `"arts -d abs_lineshapeDefine"` for further information.

ABS_LINESHAPE_FACTOR:

The line shape normalisation factor to apply. The same factor is used for all tag groups. Shall be a string. Do `"arts -d abs_lineshapeDefine"` for valid options.

ABS_LOOKUP:

Has the same functionality as the arts WSV with the same name.

Can be given either as the name of a XML file, or as a matching Matlab variable.

ABS_MODELS:

Control files including descriptions of absorption models to use (called continua in arts). This shall be a series of calls of *abs_cont_descriptionAppend* (call of *abs_cont_descriptionInit* shall be included).

Given as an array of strings. The atmlab setting ARTS_INCLUDES is recognized. A file containing standard choices is:

ARTS_INCLUDES/continua.arts

ABS_NLS:

As the arts WSV with the same name. Only needed if an absorption look-up shall be calculated. Can be set by *qarts_abs_species*.

Can be given either as the name of a XML file, or as a matching Matlab variable.

ABS_NLS_PERT:

As the arts WSV with the same name. Only needed if an absorption look-up shall be calculated. See *qarts_set_abs_lookup* for simple setting of this field.

Can be given either as the name of a XML file, or as a matching Matlab variable. Empty ([]) signifies no perturbations.

ABS_P:

As the arts WSV with the same name. Only needed if an absorption look-up shall be calculated. See *qarts_set_abs_lookup* for simple setting of this field.

Can be given either as the name of a XML file, or as a matching Matlab variable.

ABS_SPECIES:

Specification of absorption species. Arts requires in many cases that H2O and N2 are included. This is a structure array defining species and associated retrieval variables. These sub-fields are defined:

<TAG> Tag group data, following *arts_tgs_cnvr*.

<ATMDATA> VMR data for the species. The input shall follow the atmdata format, defined in *isatmdata*. The data specified here are not directly given to arts, it can only be used to set-up *VMR_FIELD*. This step is handled by *qarts_vmr_field*. The field is accordingly not mandatory. The main usage of this field should be to import data of climatology character. Can be given as a variable or a file saved through *gf_save*.

<RETRIEVE> If set to true the species is retrieved. Otherwise the species is not retrieved (what a surprise!).

<UNIT> Retrieval unit. Allowed choices are 'rel', 'vmr', 'nd', and 'logrel'. For some more information:
arts -d jacobianAddAbsSpecies.

<GRIDS> Retrieval grids for the species. An array of vectors of length 3: {p_grid,lat_grid,lon_grid}. Grids for dimensions not used shall be empty.

<SX> Covariance matrix of a priori knowledge for the species. Size must match the grid field. Data must match <UNIT>. A matrix, that can be sparse.

<L2> Flag for any function creating L2 data. See comments for *L2_EXTRA*. If set to true, the retrieved state for the species will be included in the L2 output. Otherwise not. This field has no importance if RETRIEVE is false.

Only the field TAG must be present if no retrievals are performed. The fields UNIT, GRIDS, SX and L2 can be left undefined if the species is not retrieved.

ABS_T:

As the arts WSV with the same name. Only needed if an absorption look-up shall be calculated. See *qarts_set_abs_lookup* for simple setting of this field.

Can be given either as the name of a XML file, or as a matching Matlab variable.

ABS_T_PERT:

As the arts WSV with the same name. Only needed if an absorption look-up shall be calculated. See *qarts_set_abs_lookup* for simple setting of this field.

Can be given either as the name of a XML file, or as a matching Matlab variable. Empty ([]) signifies no perturbations.

ABS_VMRS:

As the arts WSV with the same name. Only needed if an absorption look-up shall be calculated. See *qarts_set_abs_lookup* for simple setting of this field.

Can be given either as the name of a XML file, or as a matching Matlab variable.

ANTENNA_DIM:

As the arts WSV with the same name.

This field can be ignored, depending on SENSOR_RESPONSE.

ATMOSPHERE_DIM:

As the arts WSV with the same name.

BATCH:

Batch calculations. Defined by a structure, described in *qartsBatch*. Type 'qinfo(@qartsBatch);' for further information. Batch calculations are not started automatically (in e.g. *arts_y*), but must be selected specifically (most easily done by using *arts_batch*).

CLOUDBOX_DO:

Boolean to activate the cloud box (scattering calculations), or not.

{}: Nothing is done. Relevant data are assumed to be specified by inclusion files.

0: Call of *cloudboxOff* is included.

1: Action follows setting of field *CLOUDBOX*.

CLOUDBOX:

Handling of cloudbox/scattering. Defined by a structure, described in *qartsCloudbox*. Type 'qinfo(@qartsCloudbox);' for further information.

EMISSION_AGENDA:

As the arts WSV with the same name. WSMs are listed as an array of strings, with possible arguments.

F_GRID:

Has the same functionality as the arts WSV with the same name.

Can be given either as the name of a XML file, or as a matching variable.

FFIT:

Structure for specification of frequency fit retrievals. No retrieval is made if field is empty or sub-field RETRIEVAL is set to false. The WSM used is *jacobianAddFreqShiftAndStretch*. These sub-fields are defined:

<RETRIEVE> Flag to activate frequency retrieval

<DF> Size for numerical perturbation. See used WSM.

<ORDER> Order of frequency fit, max value is 1 (0=shift, 1=stretch).

<SX> Covariance matrix of a priori knowledge for frequency shift and stretch. A 1x1 or 2x2 matrix, depending on ORDER.

<L2> Flag for any function creating L2 data. See comments for *L2_EXTRA*. If set to true, the retrieved frequency fit variables will be included in the L2 output. Otherwise not. This field has no importance if RETRIEVE is false.

INCLUDES:

Paths to control files to be included. These files will be included at the top of the control file, only preceded by WSMS_AT_START. Given as an array of strings.

The atmlab setting ARTS_INCLUDES is recognized. To include the standard arts general definition file,
select: {'ARTS_INCLUDES/general.arts'}

INPUT_FILE_FORMAT:

The file format for arts input files. That is, the format of the files created in matlab to be read by arts. Possible options are 'binary', and 'double'. The binary option, that is default, should be most efficient. Use 'double' if you want to visually inspect the files generated. (The option 'float' is not allowed, as this is not always sufficient for frequency data.)

IY_AUX_DO:

As the arts WSV with the same name.

IY_CLEARSKY_AGENDA:

As the arts WSV with the same name. WSMs are listed as an array of strings.

IY_SPACE_AGENDA:

As the arts WSV with the same name. WSMs are listed as an array of strings, with possible arguments. See PPATH_STEP_AGENDA for a practical example on format to use.

J_DO:

Boolean to include calculation of jacobians.

{ }: NOthing is done. Relevant data are assumed to be specified by inclusion files.

0: Call of *jacobianOff* is included.

1: Action follows setting of field *J*.

J_UNIT:

Matches the WSV *jacobian_unit*. For further information: arts -d jacobian_unit

LAT_GRID:

Has the same functionality as the arts WSV with the same name, with the difference that a scalar value is accepted when ATMOSPHERE_DIM = 1. It could be needed to set such a scalar value when *qarts_vmr_field* and similar functions are used.

Can be given either as the name of a XML file, or as a matching Matlab variable.

LON_GRID:

Has the same functionality as the arts WSV with the same name, with the difference that a scalar value is accepted when ATMOSPHERE_DIM = 1. It could be needed to set such a scalar value when *qarts_vmr_field* and similar functions are used.

Can be given either as the name of a XML file, or as a matching Matlab variable.

L2_EXTRA:

Information to functions repacking retrieval information. Such a product is normally denoted as L2 data. This field lists data to be included beside the direct retrieval quantities, for which their L2 field has the same functionality. The information is given as string array, e.g.:

```
Q.L2_EXTRA = {'cost','mresp','ptz'}
```

There is no general L2 function and the possible data output (and coding) differs between the functions.

MBLOCK_AA_GRID:

Has the same functionality as the arts WSV with the same name. This field can be ignored, depending on setting of SENSOR_RESPONSE.

If the antenna dimension is 1, this variable can be left as {}. For 2D antennas it has to be set even if the sensor does not include an antenna.

Can be given either as the name of a XML file, or as a Matlab variable.

MBLOCK_ZA_GRID:

Has the same functionality as the arts WSV with the same name. This has to be set even if the sensor does not include an antenna.

Can be given either as the name of a XML file, or as a Matlab variable.

OUTPUT_FILE_FORMAT:

As the arts WSV with the same name. That is, the format for files created by arts. Possible options are 'binary' and 'ascii'. The binary option should in general be most efficient.

POINTING:

Structure for specification of pointing fit retrievals. No retrieval is made if field is empty or sub-field RETRIEVAL is set to false. The WSM used is *jacobianAddPointing*. These sub-fields are defined:

<RETRIEVE> Flag to activate pointing retrieval.

<DZA> Size for numerical perturbation. See used WSM.

<POLY_ORDER> Order of polynomial to describe pointing errors.

<SX> Covariance matrix of a priori knowledge for pointing fit variables. A square matrix with POLY_ORDER+1.

<L2> Flag for any function creating L2 data. See comments for *L2_EXTRA*. If set to true, the retrieved pointing variables will be included in the L2 output. Otherwise not. This field has no importance if RETRIEVE is false.

POLYFIT:

Structure for specification of polynomial baseline fits. No retrieval is made if field is empty or sub-field RETRIEVAL is set to false. The WSM used is *jacobianAddPolyfit*. All no_XXX_variation arguments of the WSM are set to default value. The different polynomial coefficients are assumed to be uncorrelated. These sub-fields are defined:

<RETRIEVE> Flag to activate pointing retrieval

<ORDER> Order of polynomial fit.

<SX0> Covariance matrix of a priori knowledge for coefficient of order zero. There shall be such a matrix for each coefficient order until:

<SXn> Covariance matrix of a priori knowledge for coefficient of order POLY_ORDER. The last required covariance matrix.

<L2> Flag for any function creating L2 data. See comments for *L2_EXTRA*. If set to true, the retrieved baseline variables will be included in the L2 output. Otherwise not. This field has no importance if RETRIEVE is false.

PPATH_LMAX:

As the arts WSV with the same name .

Can be given either as the name of a XML file, or as a Matlab variable.

PPATH_LRAYTRACE:

As the arts WSV with the same name .

Can be given either as the name of a XML file, or as a Matlab variable.

PPATH_STEP_AGENDA:

As the arts WSV with the same name .WSMs are listed as an array of strings. An example showing how an agenda definition looks like:

```
Q.PPATH_STEP_AGENDA={'ppath_stepGeometric'}
```

P_GRID:

Has the same functionality as the arts WSV with the same name.

Can be given either as the name of a XML file, or as a matching Matlab variable.

R_GEOID:

Geoid radius. A spherical geoid will be assumed if the field value is a scalar. Otherwise it is assumed that the field holds a matrix of correct size. Note that *wgs84* is part of atmlab and can be used to set the field value (e.g.

```
Q.R_GEOID=wgs84(2.Q.LAT_GRID);).
```

RAW_ATMOSPHERE:

Main file name for a raw atmosphere. See further 'arts -d AtmRawRead'. This variable is only used if USE_RAW_ATMOSPHERE = 1, but must then be set.

RAW_ATM_EXPAND_1D:

Boolean to expand an 1D raw atmosphere to set ATMOSPHERE_DIM. If set to 1, the WSM *AtmFieldsCalcExpand1D* is used instead of *AtmFieldsCalc*. This variable is only used if USE_RAW_ATMOSPHERE = 1, but must then be set.

REFR_INDEX_AGENDA:

As the arts WSV with the same name. If PPATH_STEP_AGENDA does not involve refraction, this field can be left as {}.

WSMs are listed as an array of strings. See PPATH_STEP_AGENDA for a practical example on format to use.

SENSOR_DO:

Boolean to include sensor characteristics. Otherwise monochromatic pencil beam calculations are performed. *SENSOR_POS/LOS* are used in both cases.

{}: Nothing is done. Relevant data are assumed to be specified by inclusion files.

0: Call of *sensorOff* is included.

1: Action follows setting of field *SENSOR_RESPONSE*.

SENSOR_LOS:

As the arts WSV with the same name.

SENSOR_POS:

As the arts WSV with the same name.

SENSOR_RESPONSE:

As the arts WSV with the same name. Three main options exist:

1: The first option is to specify each variable associated with the sensor individually. This field can then be the name of a XML file or a Matlab sparse matrix. Other fields that must be specified for this option include: ANTENNA_DIM, MBLOCK_ZA/AA_GRID and SENSOR_RESPONSE_F/ZA/AA/POL.

2: The name of control files to include (ARTS_INCLUDES recognised). Given as an array of strings.

3: Calculate the response from basic data. This field shall then be a structure, following the definitions in *qartsSensor*. Type 'qinfo(@qartsSensor);' for definition of required data fields. Other fields that must/may be specified here include ANTENNA_DIM and MBLOCK_ZA/AA_GRID.

SENSOR_RESPONSE_AA:

As the arts WSV with the same name. This field can be ignored, depending on setting of SENSOR_RESPONSE.

Can be given either as the name of a XML file, or as a matching Matlab variable.

SENSOR_RESPONSE_AA_GRID:

As the arts WSV with the same name. This field can be ignored, depending on setting of SENSOR_RESPONSE.

Can be given either as the name of a XML file, or as a matching Matlab variable.

SENSOR_RESPONSE_F:

As the arts WSV with the same name. This field can be ignored, depending on setting of SENSOR_RESPONSE.

Can be given either as the name of a XML file, or as a matching Matlab variable.

SENSOR_RESPONSE_F_GRID:

As the arts WSV with the same name. This field can be ignored, depending on setting of SENSOR_RESPONSE.

Can be given either as the name of a XML file, or as a matching Matlab variable.

SENSOR_RESPONSE_POL:

As the arts WSV with the same name. This field can be ignored, depending on setting of SENSOR_RESPONSE.

Can be given either as the name of a XML file, or as a Matlab variable.

SENSOR_RESPONSE_POL_GRID:

As the arts WSV with the same name. This field can be ignored, depending on setting of SENSOR_RESPONSE.

Can be given either as the name of a XML file, or as a Matlab variable.

SENSOR_RESPONSE_ZA:

As the arts WSV with the same name. This field can be ignored, depending on setting of SENSOR_RESPONSE.

Can be given either as the name of a XML file, or as a matching Matlab variable.

SENSOR_RESPONSE_ZA_GRID:

As the arts WSV with the same name. This field can be ignored, depending on setting of SENSOR_RESPONSE.

Can be given either as the name of a XML file, or as a matching Matlab variable.

STOKES_DIM:

As the arts WSV with the same name.

SURFACE_PROP_AGENDA:

As the arts WSV with the same name. WSMs are listed as an array of strings. See PPATH_STEP_AGENDA for a practical example on format to use.

T_ATMDATA:

The input shall follow the atmdata format, defined in *isatmdata*. The data specified here are not directly given to arts, it can only be used to set-up *T_FIELD*. This step is handled by *qarts_t_or_z_field*. The main usage of this field should be to import data of climatology character. Can be given as a variable or a file saved through *gf_save*.

T_FIELD:

As the arts WSV with the same name.

Can be given either as the name of a XML file, or as a matching Matlab variable.

TNOISE_C:

Thermal noise correlation. A matrix (sparse preferably) giving the correlation of thermal noise between channels. Hence, the diagonal elements shall all be one. If the thermal noise is the same for all channels and has a standard deviation of s , the covariance matrix is $s*s*TNOISE_C$.

USE_RAW_ATMOSPHERE:

Boolean to decide if T_FIELD, Z_FIELD and VMR_FIELD shall be used (option 0) or RAW_ATMOSPHERE (option 1).

VMR_FIELD:

As the arts WSV with the same name.

Can be given either as the name of a XML file, or as a matching Matlab variable.

For retrievals, the a priori state for `*ABS_SPECIES*` is determined by this field.

WSMS_AT_END:

Workspace method calls to include at the far end of the control file. As `WSMS_AT_START` beside position in control file.

WSMS_AT_START:

Workspace method calls to include at the top of the control file. These calls will be executed before inclusion of files specified in `INCLUDES`.

Method calls are specified as an cell array of strings. For example, if no inclusion files are used, these calls could be useful to include

```
{ 'VectorSet(abs_n2,[0.7808])', 'abs_cont_descriptionInit' }
```

WSMS_BEFORE_RTE:

Workspace method calls to include just before execution of `*YCALC_WSMS*` or batch core part. Accordingly, this field is considered only if spectra are calculated (ignored for e.g. pure absorption calculations). Format as for `WSMS_AT_START`.

YCALC_WSMS:

Workspace method calls for performing radiative transfer calculations. The standard choice should be that this fields includes a call of `*yCalc*`. There is no clear division between this field and `*WSMS_BEFORE_RTE*`, but for best flexibility this field should start with `*yCalc*` (or corresponding method), followed by post-processing not handled by other fields.

Accordingly, this field is considered only if spectra are calculated (ignored for e.g. pure absorption calculations). Format as for `WSMS_AT_START`.

Y_UNIT:

As the arts WSV with the same name. That is, the radiance unit.

The following options exist:

'1' : Basic radiances [W/m²/Hz/sr]

'RJBT' : Conversion to brightness temperature by the Rayleigh-Jeans approximation of the Planck function.

'PlanckBT': Conversion to brightness temperature by the Planck function.

For further information: 'arts -d y_unit'.

Z_ATMDATA:

The input shall follow the atmdata format, defined in `*isatmdata*`. The data specified here are not directly given to arts, it can only be used to set-up `*Z_FIELD*`. This step is handled by `*qarts_t_or_z_field*`. The main usage of this field should be to import data of climatology character. Can be given as a variable

or a file saved through *gf_save*.

Z_FIELD:

As the arts WSV with the same name.

Can be given either as the name of a XML file, or as a matching Matlab variable.

Z_SURFACE:

Surface altitude (above geoid). A constant altitude will be assumed if the field value is a scalar. Otherwise it is assumed that the field holds a matrix of correct size.

C The fields of O

A:

Flag to include averaging kernel matrix in X. Default is 0.

cost:

Flag to include cost values in X and to calculate cost even if solution method does not require cost values. This affects also the output to *outfids*.

dx:

Flag to include the sequence of convergence values (defined as for *stop_dx*).

e:

Flag to include in X the estimate of total retrieval error (square root of diagonal elements of S). That is, the standard deviation for the sum of observation and smoothing errors.

eo:

Flag to include in X the estimate of observation error (square root of diagonal elements of S_o).

es:

Flag to include in X the estimate of smooting error (square root of diagonal elements of S_s).

G:

Flag to include gain matrix in X (also denoted as D_y).

ga_factor_not_ok:

The factor with which the Marquardt-Levenberg factor is increased when not a lower cost value is obtained. This starts a new sub-teration. This value must be > 1 .

ga_factor_ok:

The factor with which the Marquardt-Levenberg factor is decreased after a lower cost values has been reached. This value must be > 1 .

ga_max:

Maximum value for gamma factor for the Marquardt-Levenberg method. The stops if this value is reached and cost value is still not decreased. This value must be > 0 .

ga_start:

Start value for gamma factor for the Marquardt-Levenberg method.
Type:

help oem
for a definition of the gamma factor. This value must be ≥ 0 .

itermethod:
Iteration method. Choices are 'GN' for Gauss-Newton and 'ML'
or 'LM' for Marquardt-Levenberg.

i_log:
Index of values in x that are retrieved in a log-scale (e.g. the
logarithm of VMR/VMRa (see i_rel)). The actual inversion is
performed with jacobians provided (that is, must be given to oem.m
scaled correctly), but the log-scale transformation is removed for
the error characterisation for the jacobians matching this field.
No index should be found in both i_rel and i_log.

i_rel:
Index of values in x that are retrieved in a relative/fractional
unit and a rescaling of the jacobians is needed. An example on a
relative retrieval is $x = \text{VMR}/\text{VMRa}$, where VMRa is the volume
mixing ratio for the a priori state. Accordingly, the
corresponding jacobians must describe changes with respect to the
a priori state, and a direct calculation for $x \neq x_a$ will not give
a correct results. A rescaling back to x_a is then needed and this
operation can be performed by oem.m by setting this field to the
indexes for which a rescaling is needed.

J:
Flag to include weighting function matrix in X.

jexact:
Flag to select recalculation of J after last iteration. If not set
to 1, J will correspond to x before last iteration. Also used for
the linear case.

jfast:
Flag to always calculate the Jacobian in parallel to the spectrum.
This field is only used for the Marquardt-Levenberg case. This
option can save time if the calculation of the Jacobian is very
fast and the convergence is smooth (few cases where ga has to be
increased). The advantage of this option is that the next
iteration can be started without a call of the forward model.

linear:
Flag to trigger a linear inversion. Fields like itermethod are
ignored if this option is selected. Default is non-linear (0).

maxiter:
Maximum number of iterations.

msg:

Message to put at the start of output messages. Can include e.g. number of retrieval case.

outfids:

File identifiers for output messages. Include 1 for the screen. Set to [] for no output at all.

S:

Flag to include covariance matrix for total error in X. That is, the sum of So and Ss.

So:

Flag to include covariance matrix for observation error in X.

Ss:

Flag to include covariance matrix for smoothing error in X.

stop_dx:

Convergence criterion. The iteration is halted when the change in x is < stop_dx (see Eq. 5.29 in Rodgers' book). A normalisation to the length of x is applied.

sxnorm:

Flag to internally perform a normalisation of x, based on the diagonal elements of Sx. This to avoid a pure condition number for a matrix inversion that is encountered when units are such that retrieved values vary strongly in magnitude.

The inverse of Sx must be calculated internally if this option is used and there is no use in pre-calculating *Sxinv*.

yf:

Flag to include "fitted spectrum" in X. That is, the simulated measurement matching retrieved state.

Xiter:

Flag to include all iteration states in X.

D The fields of Y

DAY:

Measurement time information. All these fields (YEAR, MONTH, ...) are numeric scalars. This information is primarily used to extract data from the climatology databases.

F:

Frequency for each value of Y. Not required information. Qpack2 uses this field only for consistency checks.

HOURL:

Optional data. Allows a more detailed specification of measurement time. Otherwise as field DAY.

HSE_P:

The reference point when enforcing hydrostatic equilibrium. The geometrical altitude (HSE_Z) is given for one pressure (HSE_P).

HSE_Z:

The reference point when enforcing hydrostatic equilibrium. The geometrical altitude (HSE_Z) is given for one pressure (HSE_P).

LATITUDE:

The geographical position of the measurement.

LONGITUDE:

The geographical position of the measurement.

MINUTE:

Optional data. Allows a more detailed specification of measurement time. Otherwise as field DAY.

MONTH:

Measurement time information. All these fields (YEAR, MONTH, ...) are numeric scalars. This information is primarily used to extract data from the climatology databases.

SECOND:

Optional data. Allows a more detailed specification of measurement time. Otherwise as field DAY.

TNOISE:

Magnitude of thermal noise, given as 1 standard deviation. A scalar or a vector having the same length as y. If a scalar, the value is applied for all spectrometer channels.

Y:

The spectrum.

YEAR:

Measurement time information. All these fields (YEAR, MONTH, ...) are numeric scalars. This information is primarily used to extract data from the climatology databases.

ZA:

Line-of-sight zenith angle for the measurement. A scalar value.

Z_PLATFORM:

Altitude (above geoid) of observation platform.
